

THE BRAINS OF THE OPERATION

Backend: Creating a Domain-Specific Language for Voice Programming

Why do we need a custom language?

Why not use Voice Assistants (Siri)?

- Limited functionality
- No feedback loops

Why not use just LLMs (ChatGPT)?

- Hallucinations: nonsensical output
- Cannot reliably perform tasks

We need a system that is correct, precise, consistent, and scalable!

Designing and Building Our Language

Our CalEvent language consists of:

- An OOP AST design, a Library of CRUD commands to the Google Calendar API, and a specification

Results and Findings:

- Our backend “sanity checks” LLM output and evaluates the code
- A constrained language allows for greater safety but less expressivity

Next Steps

Our ultimate goal:

- Create a general-purpose voice programming language that can be used in a wide variety of applications

How we can achieve this:

- “Plug in” capabilities for more domains:
 - Google Maps, Recipe Maker
- Incorporate GPL features:
 - loops, conditionals

The “Constraint-Safety Tradeoff”

Our open research question: How can we build a system that is both powerful (expressive) and safe?

You tell ClippyCal what you’d like to do...

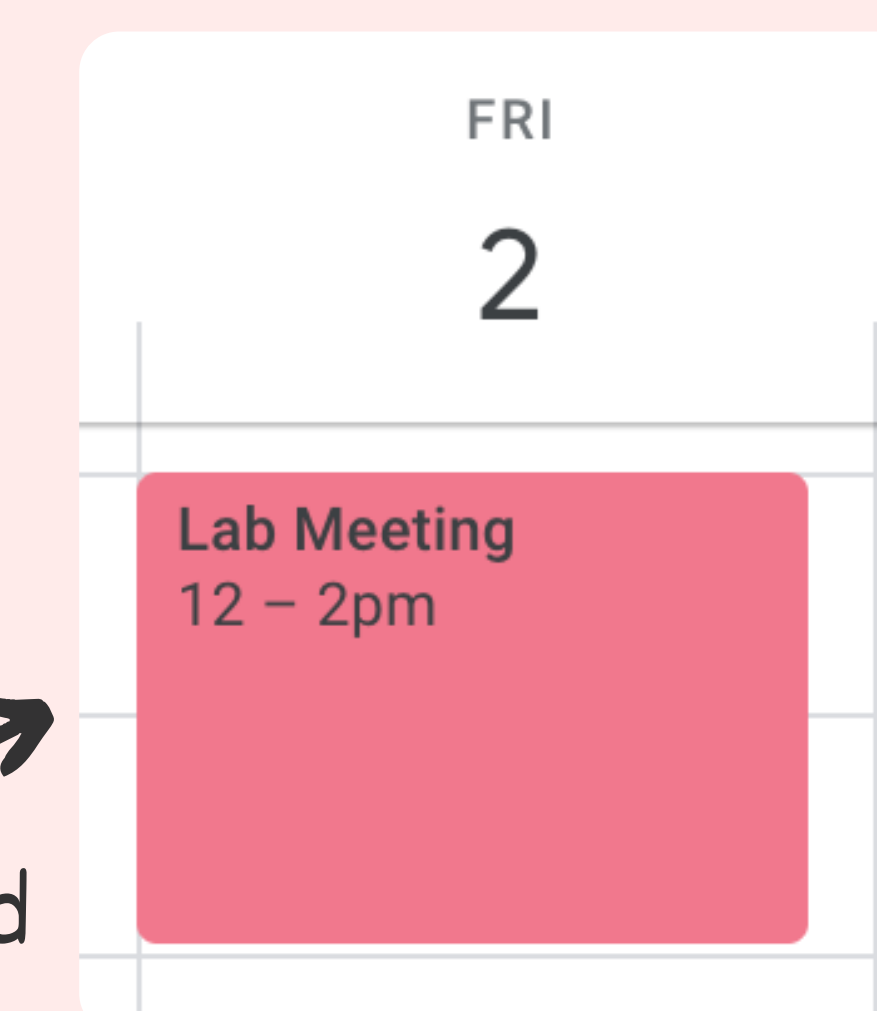

Can you schedule my 2-hour lab meeting for Friday at noon?

Frontend
Middleend

The LLM creates a program in our CalEvent language...

```
CalEvent(summary='Lab Meeting',  
start='2024-08-02T12:00:00-04:00',  
end='2024-08-02T14:00:00-04:00')  
.create()
```

Event created in the Google Calendar!

Backend

ClippyCal's CalEvent Language

Our object-oriented programming language contains these methods:

- find
- get
- create
- update
- listEvents
- delete
